M74HC123

DUAL RETRIGGERABLE MONOSTABLE MULTIVIBRATOR

- HIGH SPEED
  t_{PD} = 28 ns (TYP) at V_{CC} = 5V
- LOW POWER DISSIPATION
  STANDBY STATE I_{CC} = 4 μA (MAX.) at T_A = 25°C
  ACTIVE STATE I_{CC} = 200 μA (TYP) at V_{CC} = 5V
- HIGH NOISE IMMUNITY
  V_{NIH} = V_{NIL} = 28% V_{CC} (MIN.)
- OUTPUT DRIVE CAPABILITY
  10 LSTTL LOADS
- SYMMETRICAL OUTPUT IMPEDANCE
  $|I_{OH}|$ = I_{OL} = 4 mA (MIN.)
- BALANCED PROPAGATION DELAYS
  t_{PLH} = t_{PHL}
- WIDE OPERATING VOLTAGE RANGE
  V_{CC} (OPR) = 2V to 6V
- WIDE OUTPUT PULSE WIDTH RANGE
  t_{WOUT} = 120ns ~ 60s over at V_{CC} = 4.5V
- PIN AND FUNCTION COMPATIBLE
  WITH 54/74LS123

DESCRIPTION

The M54/74HC123 is a high speed CMOS MONOSTABLE multivibrator fabricated with silicon gate C²MOS technology. It achieves the high speed operation similar to equivalent LSTTL while maintaining the CMOS low power dissipation. There are two trigger inputs, $\overline{A}$ INPUT (negative edge) and B INPUT (positive edge). These inputs are valid for rising/falling signals, (t_r-t_f-l sec).
The device may also be triggered by using the CLR input (positive-edge) because of the Schmitt-trigger input; after triggering the output maintains the MONOSTABLE state for the time period determined by the external resistor Rx and capacitor Cx. Taking $\overline{CLR}$ low breaks this MONOSTABLE STATE. If the next trigger pulse occurs during the MONOSTABLE period it makes the MONOSTABLE period longer. Limit for values of Cx and Rx:

Cx: NO LIMIT

Rx: V_{CC} = 2.0V 5KΩ to 1MΩ
V_{CC} = 3.0V 1KΩ to 1MΩ

All inputs are equipped with protection circuits against static discharge and transient excess voltage

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Value	Unit
V_{CC}	Supply Voltage	− 0.5 to 7	V
V_I	DC Input Voltage	− 0.5 to V_{CC} + 0.5	V
V_O	DC Output Voltage	− 0.5 to V_{CC} + 0.5	V
I_{IK}	DC Input Diode Current	± 20	mA
I_{OK}	DC Output Diode Current	± 20	mA
I_O	DC Output Source Sink Current Per Output Pin	± 25	mA
I_{CC} or I_{GND}	DC V_{CC} or Ground Current	± 50	mA
P_D	Power Dissipation	500 (*)	mW
T_{stg}	Storage Temperature	− 65 to 150	°C

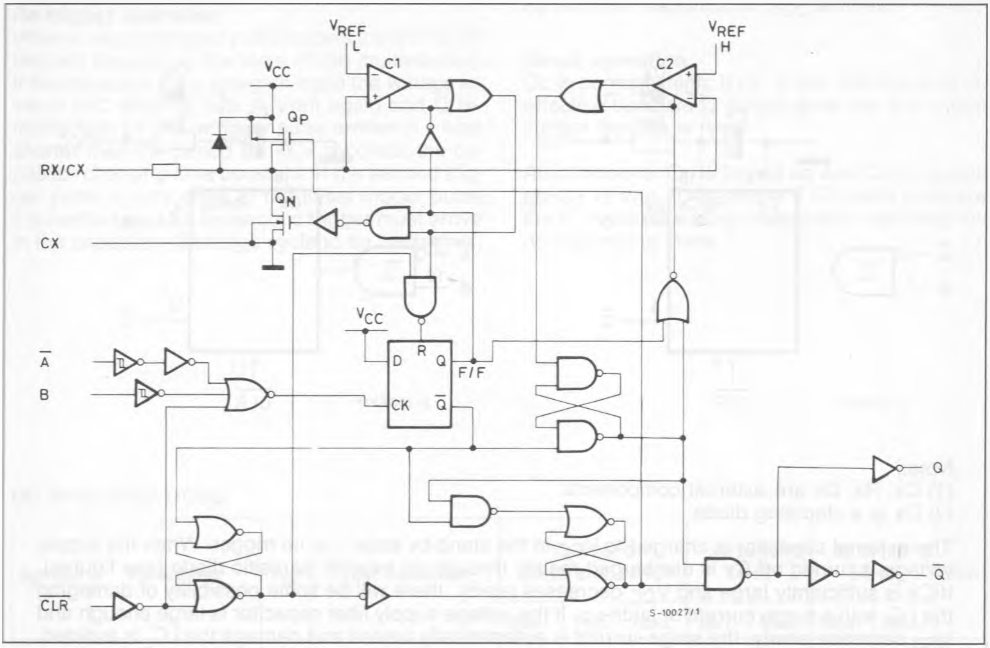
Absolute Maximum Ratings are those values beyond which damage to the device may occur. Functional operation under these condition is not implied.

(*) 500 mW: ≅ 65°C derate to 300 mW by 10 mW/°C: 65°C to 85°C

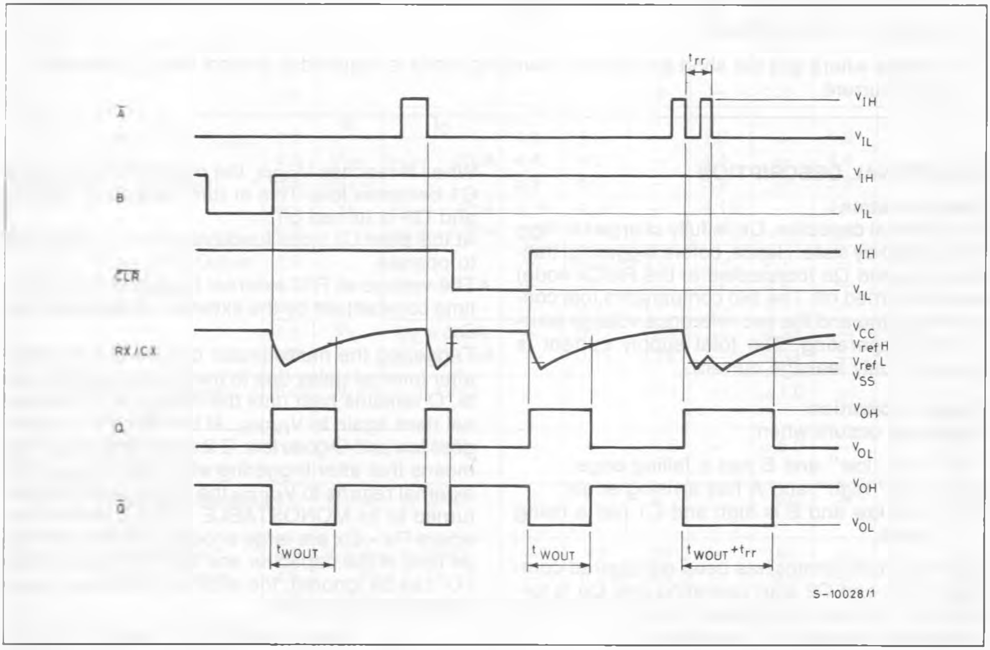
RECOMMENDED OPERATING CONDITIONS

Symbol	Parameter	Value	Unit
V_{CC}	Supply Voltage	2 to 6	V
V_I	Input Voltage	0 to V_{CC}	V
V_O	Output Voltage	0 to V_{CC}	V
T_A	Operating Temperature 74HC Series 54HC Series	− 40 to 85 − 55 to 125	°C
t_r, t_f	Input Rise and Fall Time ($\overline{CLR}$ only)	V_{CC} 2 V: 0 to 1000 V_{CC} 4.5V: 0 to 500 V_{CC} 6 V: 0 to 400	ns
Cx	External Capacitor	NO LIMITATION	
Rx	External Resistor	V_{CC} 3 V: 5K to 1M V_{CC} 3 V: 1K to 1M	Ω

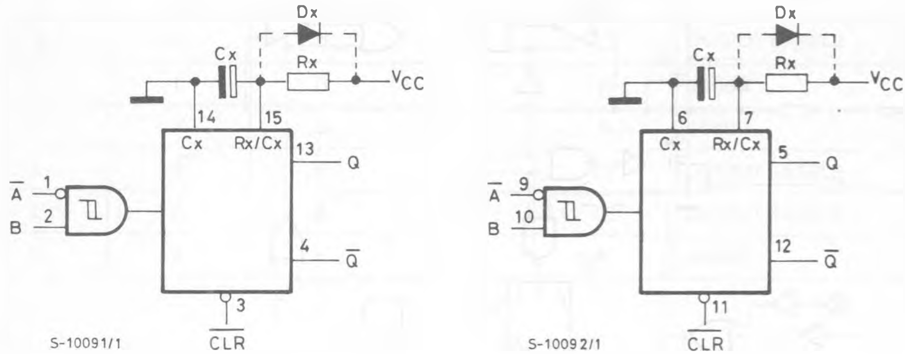
SYSTEM DIAGRAM



TIMING CHART



BLOCK DIAGRAM



Note:
(1) Cx, Rx, Dx are external components.
(2) Dx is a clamping diode

The external capacitor is charged to V_{CC} in the stand-by state, i.e. no trigger. When the supply voltage is turned off Cx is discharged mainly through an internal parasitic diode (see figures). If Cx is sufficiently large and V_{CC} decreases rapidy, there will be some possibility of damaging the I.C. with a surge current or latch-up. If the voltage supply filter capacitor is large enough and V_{CC} decrease slowly, the surge current is automatically limited and damage the I.C. is avoided. The maximum forward current of the parasitic diode is approximately 20 mA. In cases where Cx is large the time taken for the supply voltage to fall to 0.4 V_{CC} can be calculated as follows:

$t_f \geqq (V_{CC} - 0.7) \cdot Cx/20mA$

In cases where t_f is too short an external clamping diode is required to protect the I.C. from the surge current.

FUNCTIONAL DESCRIPTION

Stand-by state

The external capacitor, Cx, is fully charged to V_{CC} in the stand-by state. Hence, before triggering, transistor Qp and Qn (connected to the Rx/Cx node) are both turned off. The two comparators that control the timing and the two reference voltage sources stop operating. The total supply current is therefore only leakage current.

Trigger operation

Triggering occurs when:

1 st) A is "low" and B has a falling edge;
2 nd) B is "high" and A has a rising edge;
3 rd) A is low and B is high and C1 has a rising edge.

After the multivibrator has been retriggered comparator C1 and C2 start operating and Qn is turned on. Cx then discharges through Qn. The voltage at the node R/C external falls.

When it reaches V_{REFL} the output of comparator C1 becomes low. This in turn resets the flip-flop and Qn is turned off.
At this point C1 stops functioning but C2 continues to operate.
The voltage at R/C external begins to rise with a time constant set by the external components Rx, Cx.
Triggering the multivibrator causes Q to go high after internal delay due to the flip-flop and the gate. Q remains high until the voltage at R/C external rises again to V_{REFH}. At this point C 2 output goes low and O goes low. C 2 stops operating. That means that after triggering when the voltage R/C external returns to V_{REFH} the multivibrator has returned to its MONOSTABLE STATE. In the case where Rx • Cx are large enough and the discharge time of the capacitor and the delay time in the I.C. can be ignored, the width of the output pulse tw (out) is as follows:

$$t_{W(OUT)} = 0.46\ Cx \cdot Rx$$

FUNCTIONAL DESCRIPTION (Continued)

Re-trigger operation

When a second trigger pulse follows the first its effect will depend on the state of the multivibrator. If the capacitor Cx is being charged the voltage level of R/C external falls to Vrefl again and Q remains high i.e. the retrigger pulse arrives in a time shorter than the period Rx • Cx seconds, the capacitor charging time constant. If the second trigger pulse is very close to the initial trigger pulse it is ineffective; i.e., the second trigger must arrive in the capacitor discharge cycle to be ineffective. Hence the minimum time for a second trigger to be effective depends on V_{CC} and Cx.

Reset operation

CL is normally high. If CL is low, the trigger is not effective because Q output goes low and trigger control flip-flop is reset.

Also transistor Op is turned on and Cx is charged quicky to V_{CC}. This means if CL input goes low, the IC becomes waiting state both in operating and non operating state.
