## 400 mA Low-Drop Voltage Regulator

The NCV4276B is a 400 mA output current integrated low dropout regulator family designed for use in harsh automotive environments. It includes wide operating temperature and input voltage ranges. The device is offered with 3.3 V, 5.0 V, and adjustable voltage versions available in 2% output voltage accuracy. It has a high peak input voltage tolerance and reverse input voltage protection. It also provides overcurrent protection, overtemperature protection and inhibit for control of the state of the output voltage. The NCV4276B family is available in DPAK and D<sup>2</sup>PAK surface mount packages. The output is stable over a wide output capacitance and ESR range. The NCV4276B has improved startup behavior during input voltage transients.

### Features

- 3.3 V, 5.0 V, and Adjustable Voltage Version (from 2.5 V to 20 V) ±2% Output Voltage
- 400 mA Output Current
- 500 mV (max) Dropout Voltage (5.0 V Output)
- Inhibit Input
- Very Low Current Consumption
- Fault Protection
  - ◆ +45 V Peak Transient Voltage
  - ◆ -42 V Reverse Voltage
  - ◆ Short Circuit
  - ◆ Thermal Overload
- NCV Prefix for Automotive and Other Applications Requiring Site and Control Changes
- These are Pb-Free Devices

## PIN FUNCTION DESCRIPTION

Pin No.	Symbol	Description
1	I	Input; Battery Supply Input Voltage.
2	INH	Inhibit; Set low-to inhibit.
3	GND	Ground; Pin 3 internally connected to heatsink.
4	NC / VA	Not connected for fixed voltage version / Voltage Adjust Input for adjustable voltage version; use an external voltage divider to set the output voltage
5	Q	Output: Bypass with a capacitor to GND. See Figures 3 to 7 and Regulator Stability Considerations section.

## MAXIMUM RATINGS\*

Rating	Symbol	Min	Max	Unit
Input Voltage	$V_I$	-42	45	V
Input Peak Transient Voltage	$V_I$	-	45	V
Inhibit INH Voltage	$V_{INH}$	-42	45	V
Voltage Adjust Input VA	$V_{VA}$	-0.3	10	V
Output Voltage	$V_Q$	-1.0	40	V
Ground Current	$I_q$	-	100	mA
Input Voltage Operating Range	$V_I$	$V_Q + 0.5 \text{ V}$ or 4.5 V (Note 1)	40	V
ESD Susceptibility	(Human Body Model)	-	4.0	kV
	(Machine Model)	-	250	V
	(Charged Device Model)	-	1.25	kV
Junction Temperature	$T_J$	-40	150	°C
Storage Temperature	$T_{stg}$	-50	150	°C

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

\*During the voltage range which exceeds the maximum tested voltage of I, operation is assured, but not specified. Wider limits may apply. Thermal dissipation must be observed closely.

## LEAD TEMPERATURE SOLDERING REFLOW (Note 2)

Lead Temperature Soldering	$T_{SLD}$			°C
Reflow (SMD styles only), Leaded, 60–150 s above 183, 30 s max at peak		-	240	
Reflow (SMD styles only), Lead Free, 60–150 s above 217, 40 s max at peak		-	265	
Wave Solder (through hole styles only), 12 sec max		-	310	

## THERMAL CHARACTERISTICS

### Circuit Description

The NCV4276B is an integrated low dropout regulator that provides a regulated voltage at 400 mA to the output. It is enabled with an input to the inhibit pin. The regulator voltage is provided by a PNP pass transistor controlled by an error amplifier with a bandgap reference, which gives it the lowest possible dropout voltage. The output current capability is 400 mA, and the base drive quiescent current is controlled to prevent oversaturation when the input voltage is low or when the output is overloaded. The regulator is protected by both current limit and thermal shutdown. Thermal shutdown occurs above 150°C to protect the IC during overloads and extreme ambient temperatures.

### Regulator

The error amplifier compares the reference voltage to a sample of the output voltage ( $V_O$ ) and drives the base of a PNP series pass transistor via a buffer. The reference is a bandgap design to give it a temperature-stable output. Saturation control of the PNP is a function of the load current and input voltage. Oversaturation of the output power device is prevented, and quiescent current in the ground pin is minimized. See Figure 4, Test Circuit, for circuit element nomenclature illustration.

### Regulator Stability Considerations

The input capacitors ( $C_{I1}$  and  $C_{I2}$ ) are necessary to stabilize the input impedance to avoid voltage line influences. Using a resistor of approximately 1.0  $\Omega$  in series with  $C_{I2}$  can stop potential oscillations caused by stray inductance and capacitance.

The output capacitor helps determine three main characteristics of a linear regulator: startup delay, load transient response and loop stability. The capacitor value and type should be based on cost, availability, size and temperature constraints. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures ( $-25^\circ\text{C}$  to  $-40^\circ\text{C}$ ), both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet usually provides this information.

The value for the output capacitor  $C_O$ , shown in Figure 3, should work for most applications; see also Figures 5 to 7 for output stability at various load and Output Capacitor ESR conditions. Stable region of ESR in Figures 5 to 7 shows ESR values at which the LDO output voltage does not have any permanent oscillations at any dynamic changes of output load current. Marginal ESR is the value at which the output voltage waving is fully damped during four periods after the load change and no oscillation is further observable.

ESR characteristics were measured with ceramic capacitors and additional series resistors to emulate ESR. Low duty cycle pulse load current technique has been used to maintain junction temperature close to ambient temperature.

Minimum ESR for  $C_O = 22 \mu\text{F}$  is native ESR of ceramic capacitor with which the fixed output voltage devices are performing stable. Murata ceramic capacitors were used, GRM32ER71C226KE18 (22  $\mu\text{F}$ , 16 V, X7R, 1210), GRM31CR71C106KAC7 (10  $\mu\text{F}$ , 16 V, X7R, 1206).

### Calculating Bypass Capacitor

If usage of low ESR ceramic capacitors is demand in case of Adjustable Regulator, connect the bypass capacitor  $C_b$  between Voltage Adjust pin and Q pin according to Applications circuit at Figure 4.

Parallel combination of bypass capacitor  $C_b$  with the feedback resistor  $R_1$  contributes in the device transfer function as an additional zero and affects the device loop stability, therefore its value must be optimized. Attention to the Output Capacitor value and its ESR must be paid. See also Stability in High Speed Linear LDO Regulators Application Note, AND8037/D for more information.

Optimal value of bypass capacitor is given by following expression

$$C_b = \frac{1}{2 \times \pi \times f_z \times R_1} \cdot (F)$$

where

$R_1$  = the upper feedback resistor

$f_z$  = the frequency of the zero added into the device transfer function by  $R_1$  and  $C_b$  external components.

Set the  $R_1$  resistor according to output voltage requirement. Chose the  $f_z$  with regard on the output capacitance  $C_O$ , refer to the table below.

$C_O$ ( $\mu\text{F}$ )	10	22	47	100
$f_z$ Range (kHz)	20 - 50	14 - 35	10 - 20	7 - 14

Ceramic capacitors and its part numbers listed bellow have been used as low ESR output capacitors  $C_O$  from the table above to define the frequency ranges of additional zero required for stability.

GRM31CR71C106KAC7 (10  $\mu\text{F}$ , 16 V, X7R, 1206)

GRM32ER71C226KE18 (22  $\mu\text{F}$ , 16 V, X7R, 1210)

GRM32ER61C476ME15 (47  $\mu\text{F}$ , 16 V, X5R, 1210)

GRM32ER60J107ME20 (100  $\mu\text{F}$ , 6.3 V, X5R, 1210)

### Inhibit Input

The inhibit pin is used to turn the regulator on or off. By holding the pin down to a voltage less than 1.8 V, the output of the regulator will be turned off. When the voltage on the Inhibit pin is greater than 2.8 V, the output of the regulator will be enabled to power its output to the regulated output voltage. The inhibit pin may be connected directly to the input pin to give constant enable to the output regulator.

### Setting the Output Voltage (Adjustable Version)

The output voltage range of the adjustable version can be set between 2.5 V and 20 V. This is accomplished with an external resistor divider feeding back the voltage to the IC back to the error amplifier by the voltage adjust pin VA.

The internal reference voltage is set to a temperature stable reference of 2.5 V.

The output voltage is calculated from the following formula. Ignoring the bias current into the VA pin:

$$V_Q = [(R_1 + R_2) * V_{ref}] / R_2$$

Use  $R_2 < 50\text{ k}$  to avoid significant voltage output errors due to VA bias current.

Connecting VA directly to Q without R1 and R2 creates an output voltage of 2.5 V.

Designers should consider the tolerance of R1 and R2 during the design phase.

The input voltage range for operation (pin 1) of the adjustable version is between  $(V_Q + 0.5\text{ V})$  and 40 V. Internal bias requirements dictate a minimum input voltage of 4.5 V. The dropout voltage for output voltages less than 4.0 V is  $(4.5\text{ V} - V_Q)$ .

### Calculating Power Dissipation in a Single Output Linear Regulator

The maximum power dissipation for a single output regulator (Figure 28) is:

$$P_{D(max)} = [V_{I(max)} - V_{Q(min)}] I_{Q(max)} + V_{I(max)} I_q \quad (1)$$

where

- $V_{I(max)}$  is the maximum input voltage,
- $V_{Q(min)}$  is the minimum output voltage,
- $I_{Q(max)}$  is the maximum output current for the application,
- $I_q$  is the quiescent current the regulator consumes at  $I_{Q(max)}$ .

Once the value of  $P_{D(max)}$  is known, the maximum permissible value of  $R_{\theta JA}$  can be calculated:

$$R_{\theta JA} = \frac{150^{\circ}\text{C} - T_A}{P_D} \quad (2)$$

The value of  $R_{\theta JA}$  can then be compared with those in the package section of the data sheet. Those packages with  $R_{\theta JA}$  less than the calculated value in Equation 2 will keep the die temperature below 150°C.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 28. Single Output Regulator with Key Performance Parameters Labeled

### Heatsinks

A heatsink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of  $R_{\theta JA}$ :

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CS} + R_{\theta SA} \quad (3)$$

where

- $R_{\theta JC}$  is the junction-to-case thermal resistance,
- $R_{\theta CS}$  is the case-to-heatsink thermal resistance,
- $R_{\theta SA}$  is the heatsink-to-ambient thermal resistance.

$R_{\theta JC}$  appears in the package section of the data sheet. Like  $R_{\theta JA}$ , it too is a function of package type.  $R_{\theta CS}$  and  $R_{\theta SA}$  are functions of the package type, heatsink and the interface between them. These values appear in data sheets of heatsink manufacturers.

Thermal, mounting, and heatsinking considerations are discussed in the ON Semiconductor application note AN1040/D.

**Thermal Model**

A discussion of thermal modeling is in the ON Semiconductor web site: <http://www.onsemi.com/pub/collateral/BR1487-D.PDF>.

NOTE: Bold face items represent the package without the external thermal system.

The Cauer networks generally have physical significance and may be divided between nodes to separate thermal behavior due to one portion of the network from another. The Foster networks, though when sorted by time constant (as above) bear a rough correlation with the Cauer networks, are really only convenient mathematical models. Cauer networks can be easily implemented using circuit simulating tools, whereas Foster networks may be more easily implemented using mathematical tools (for instance, in a spreadsheet program), according to the following formula:

$$R(t) = \sum_{i=1}^n R_i (1 - e^{-t/\tau_i})$$

## PACKAGE DIMENSIONS

**D<sup>2</sup>PAK 5**  
CASE 936A-02  
ISSUE C

**NOTES:**

1. DIMENSIONING AND TOLERANCING PER ANSI Y14.5M, 1982.
2. CONTROLLING DIMENSION: INCH.
3. TAB CONTOUR OPTIONAL WITHIN DIMENSIONS A AND K.
4. DIMENSIONS U AND V ESTABLISH A MINIMUM MOUNTING SURFACE FOR TERMINAL 6.
5. DIMENSIONS A AND B DO NOT INCLUDE MOLD FLASH OR GATE PROTRUSIONS. MOLD FLASH AND GATE PROTRUSIONS NOT TO EXCEED 0.025 (0.635) MAXIMUM.

DIM	INCHES		MILLIMETERS	
	MIN	MAX	MIN	MAX
